Protocol Summary

PasswordStore is a protocol dedicated to storage and retrieval of a user's passwords. The protocol is designed to be used by a single user, and is not designed to be used by multiple users. Only the owner should be able to set and access this password.

Disclaimer

The YOUR_NAME_HERE team makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the Solidity implementation of the contracts.

Risk Classification

		Impact		
		High	Medium	Low
Likelihood	High	H	H/M	M
	Medium	H/M	M	M/L
	Low	M	M/L	L

We use the CodeHawks severity matrix to determine severity. See the documentation for more details.

```

Protocol Summary

PasswordStore is a protocol dedicated to storage and retrieval of a user's passwords. The protocol is designed to be used by a single user, and is not designed to be used by multiple users. Only the owner should be able to set and access this password.

Roles

- Owner: Is the only one who should be able to set and access the password.

For this contract, only the owner should be able to interact with the contract.

Findings

High

[H-1] Storing the password on-chain makes it visable to anyone, and no longer private

Description: All data stored on-chain is visible to anyone, and can be read directly from the blockchain. The `PasswordStore : : s_password` variable is intended to be a private variable and only accessed through the `PasswordStore : : getPassword` function, which is intended to be only called by the owner of the contract.

We show one such method of reading any data off chain below.

Impact: Anyone can read the private password, severely breaking the functionality of the protocol

Proof of Concept: (Proof of Code)

1. Create a locally running chain

```
1 make anvil
```

2. Deploy the contract to the chain

```
1 make deploy
```

3. Run the storage tool

We use 1 because that's the storage slot of `s_password` in the contract.

```
1 cast storage <ADDRESS_HERE> 1 --rpc-url http://127.0.0.1:8545
```

You'll get an output that looks like this:

[illegible]

You can then parse that hex to a string with:

[illegible]

And get an output of:

```
1 myPassword
```

Recommended Mitigation: Due to this, the overall architecture of the contract should be rethought. One could encrypt the password off-chain, and then store the encrypted password on-chain. This would require the user to remember another password off-chain to decrypt the password. However, you'd also likely want to remove the view function as you wouldn't want the user to accidentally send a transaction the the password that decrypts your password.

[H-2] PasswordStore__setPassword has no access controls, meaning a non-owner could change the password

Description: The `PasswordStore__setPassword` function is set to be an `external` function, however, the natspec of the function and overall purpose of the smart contract is that `This function allows only the owner to set a new password.`

```
1 function setPassword(string memory newPassword) external {
2 @> // @audit - There are no access controls
3     s_password = newPassword;
4     emit SetNetPassword();
5 }
```

Impact: Anyone can set/change the password of the contract, severely breaking the contract intended functionality.

Proof of Concept:

Add the following to the `PasswordStore.t.sol` test file.

Code

```
1 function test_anyone_can_set_password(address randomAddress) public
    {
```

```
2         vm.assume(randomAddress != owner);
3         vm.prank(randomAddress);
4         string memory expectedPassword = "myNewPassword";
5         passwordStore.setPassword(expectedPassword);
6
7         vm.prank(owner);
8         string memory actualPassword = passwordStore.getPassword();
9         assertEq(actualPassword, expectedPassword);
10    }
```

Recommended Mitigation: Add an access control conditional to the `setPassword` function.

```
1    if(msg.sender != s_owner) {
2        revert PasswordStore__NotOwner();
3    }
```

Medium

Low

Informational

[I-1] PasswordStore::getPassword natspec indicates a parameter that doesn't exist, causing the natspec to be incorrect

Description: `PasswordStore::getPassword` function signature is `getPassword()` which the natspec say it should be `getPassword(string)`.

```
1    /*
2     * @notice This allows only the owner to retrieve the password.
3     * @param newPassword The new password to set.
4     */
5    function getPassword() external view returns (string memory) {
6        if (msg.sender != s_owner) {
7            revert PasswordStore__NotOwner();
8        }
9        return s_password;
10    }
```

Impact: The natspec is incorrect.

Recommended Mitigation: remove the incorrect natspec line.

```
1    -    * @param newPassword The new password to set.
```
